

Registration Exercise

Write the frontend for a registration page, this page should contain a simple form consisting of an e-mail field, date of birth field, and a password field.

We expect that this test will take around two hours. Don't worry if you are unable to complete all requirements, submit as much as you are able.

Requirements

- Write a simple backend in PHP that handles the form and shows a welcome page (you are not required to handle validation here for this exercise). The welcome page can be a simple screen stating “Welcome <email>“.
- Client side validation - all fields are required, the date of birth is not in the future, and that the passwords match.
- Responsive design, as per the above screenshots. The resolution at which the logo and field orientation changes is left to you.
- Prevent duplicate submissions by disabling the register button.
- Use ajax to submit the form, place a spinner adjacent to the button while the submission is in progress, show a simple alert stating “Welcome <email>” upon successful response from the server - do not show the welcome page after the alert.
- All the files required to run the app should be added to Github (or equivalent).
- Please supply a url to your repo when you are finished.

What we are looking for

- Secure implementation - document/implement any security requirements.
- Cross browser support - you can decide which browsers - document your reasoning.
- “Atomic” commits with good commit messages.
- Accessible, semantic, valid HTML.
- Document reasons for the inclusion of any third party dependencies - if you have used any.
